## **CLAIMS**:

## We claim:

An autonomic buffer configuration method comprising the steps of:
 monitoring data flowing through buffers in a communications system;
 recording in at least one buffer profile different data sizes for different ones of
 said data flowing through said buffers during an established interval of time;

computing an optimal buffer size based upon a specification of a required percentage of times a buffer must be able to accommodate data of a particular size; and,

re-sizing at least one of said buffers without re-initializing said at least one resized buffer.

- 2. The method of claim 1, wherein said recording step further comprises the step of varying delays between consecutive input/output operations in said communications system to affect how much data flows between said communications system and an application coupled to said communications system.
- 3. The method of claim 1, wherein said monitoring step comprises the step of monitoring said data for each connection in said communications system.
- 4. The method of claim 3, wherein said computing step comprises the step of computing an optimal buffer size sufficient to maintain long-lived communication.

- 5. The method of claim 4, further comprising the step of establishing a buffer size for newly opened connections in said communications system based upon said computed optimal buffer size.
- 6. A profile processor disposed within an autonomic buffer configuration system comprising:

a performance monitor arranged to monitor data flowing through at least one buffer in a communications system;

a reporting tool configured to generate at least one buffer profile based upon monitored information produced by said performance monitor;

a buffer size calculator programmed to compute an optimal buffer size for said at least one buffer based upon said at least one buffer profile; and,

a buffer resizing component coupled to said at least one buffer and programmed to dynamically resize said at least one buffer to said optimal buffer size without reinitializing said buffer.

- 7. The profile processor of claim 6, wherein said at least one buffer is selected from the group consisting of an application-level buffer and a kernel-level buffer.
- 8. The profile processor of claim 6, wherein said data comprises at least one of requests and responses to said requests.

- 9. The profile processor of claim 6, wherein said communications system is disposed within one of a Web server and an applications server.
- 10. The profile processor of claim 7, wherein said performance monitor comprises a configuration for performing an analysis of an amount of data passed between said application-layer buffer and said kernel-layer buffer.
- 11. The profile processor of claim 8, wherein said performance monitor comprises a configuration for performing at least one of (1) a statistical analysis of request sizes for an interval of time for said communications system, (2) a statistical analysis of request sizes for an interval of time for individual connections in said communications system, (3) a statistical analysis of inserting delay durations of varying lengths between consecutive input/output operations in said communications system, and (4) a statistical analysis of patterns of requests and an ordering of said requests in said patterns.
- 12. The profile processor of claim 6, wherein said monitored information is weighted in said at least one buffer profile.
- 13. The profile processor of claim 6, further comprising a profile aggregator configured to combine individual buffer profiles to produce a single profile for use by said calculator in computing an optimal buffer size.

14. A machine readable storage having stored thereon a computer program for autonomic buffer configuration, the computer program comprising a routine set of instructions which when executed by the machine cause the machine to perform the steps of:

monitoring data flowing through buffers in a communications system;
recording in at least one buffer profile different data sizes for different ones of said data flowing through said buffers during an established interval of time;

computing an optimal buffer size based upon a specification of a required percentage of times a buffer must be able to accommodate data of a particular size; and,

re-sizing at least one of said buffers without re-initializing said at least one resized buffer.

- 15. The machine readable storage of claim 14, wherein said recording step further comprises the step of varying delays between consecutive input/output operations in said communications system to affect how much data flows between said communications system and an application coupled to said communications system.
- 16. The machine readable storage of claim 14, wherein said monitoring step comprises the step of monitoring said data for each connection in said communications system.

- 17. The machine readable storage of claim 16, wherein said computing step comprises the step of computing an optimal buffer size sufficient to maintain long-lived communication.
- 18. The machine readable storage of claim 17, further comprising the step of establishing a buffer size for newly opened connections in said communications system based upon said computed optimal buffer size.
